Recall the 3 quantitative approaches to measuring gerrymandering discussed in lecture:
1. Mean - Median Score (Grofman, 1983)
2. Efficiency Gap (Stephanopolous and McGee, 2015)
3. Ensembles / Extreme Outliers
Use the following table to practice applying the first two techniques.

| District | D Votes | R Votes | Result |
|---|---|---|---|
| 1 | 62 | 38 | D wins |
| 2 | 55 | 45 | D wins |
| 3 | 44 | 56 | R wins |
| 4 | 47 | 53 | R wins |
| 5 | 46 | 54 | R wins |
| **Total** | **254** | **246** | |

## Q1. Mean-Median Score

Calculate the mean-median score associated with this particular district breakdown of votes.

```
# add code for Q1 here
```

## Q2. Efficiency Gap

Calculate the Efficiency Gap (EG) associated with this particular district breakdown of votes.

*Tip*: it may be helpful to write a function that takes a vector of votes across districts for party A and vector of votes for the party B and returns a vector of the number votes wasted by party A across districts.

```
# add code for Q2 here
```
